

INTRODUCTION AND BACKGROUND

35

30

I am addressing the genetic basis of phenotype changes with environment (phenotypic plasticity) in Arabidopsis thaliana. A. thaliana is an annual plant, i.e. that grows and reproduces all within a year. Seasonal cues, such as photoperiod and temperature, tell the plant when it's time to germinate and flower. For A. thaliana, the response to those cues is variable. Plants flower in the spring in response to long days. When their seeds germinate varies among populations. Most germinate the following fall, while others spend the winter as a seed. The cold temperatures of winter experienced by overwintering seeds acts as a warning sign to hurry up and flower the following spring (Figure 1). I am examining the sequences differences among three genetic inbred strains (lines) with dramatically different sensitivities to seasonal cues and specifically the methylation patterns of their cytosines and adenines

I used a set of recombinant inbred lines of *Arabidopsis* thaliana. Recombinant inbred lines (RIL) are the result of crossing two genetically uniform strains (Cal-0 & Tac), allowing recombination to occur in the resulting hybrid then self-fertilizing each recombinant offspring to make inbred lines where all lines have fixed and widely variable recombination events. Just like humans, recombination is a way for a plant to generate a new combination of genes that can affect the expression of the protein product of those genes and thus their phenotypes. To determine how recombination and methylation may have influenced gene expression and sensitivity to the environment we are sequencing 3 RILs with dramatically different phenotypic responses to cold treatment of seeds as well as gene expression responses to environment (Figure 2) along with one parental strain. The goal of this experiment is to find the rearrangements that caused phenotypic changes among the three RILs and ask if commonly methylated adenines and cytosines were important in the subsequent gene expression differences.

Sequencing Data Analysis

We used EPI2ME software (Metrichor) to separate all of the reads by bard Figure 4). To determine how much of each chromosome we have sequenc TAIR 10.0 reference genome to align pooled and barcoded sequences again mitochondrial genomes as well as the 5 chromosomes (Table 1A). We did un-pooled sequence data, to assess how much of each chromosome was se strain Table 1B). We used the program UGene to visualize our reads align reference sequence (Figure 6).

Still to do:

We can use the minION flow cell for 72 more hours to collect more sequence information. • We will continue to analyze the data for methylation patterns

• To quantify the gene expression we will perform qPCR assays on these 4 strains plus other less extreme RILs

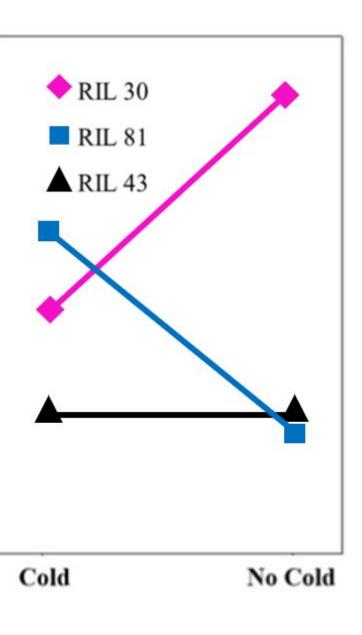

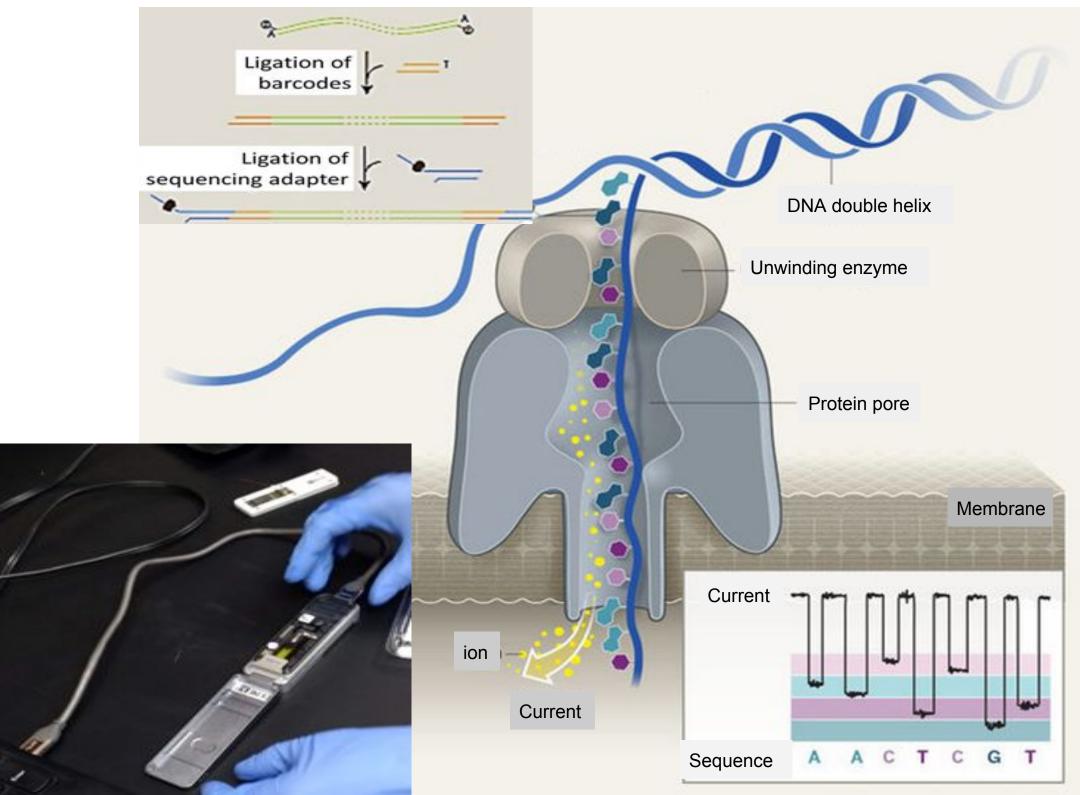

Figure 2: Reaction norm graph showing the degree and direction of phenotypic plasticity to the cold treatment (4C for 11 days) of seeds. Three kinds of plasticity to the seed treatment are shown, the sensitive negative (C-NC) line, RIL 30, sensitive positive, RIL81 and insensitive, RIL 43.

The Oxford Nanopore Technologies (ONT) minION is a portable device that plugs into a computer or phone via a USB port. It uses an ionic current that passes through each nanopore on the flow cell membrane and measures the changes in that current as DNA base pairs pass through it (Figure 3). These measurable changes in the ionic current can be used to determine what biological molecule it is, that is, what base pairs are flowing through. It sequences DNA in real time, so base calling (nucleotide identification) occurs at the same time.

This research project was supported by the Office of Student Research and Creative Activity (OSRCA). Funding was also provided by the University of Oshkosh Honors College. The Gene Team helped make this entire project possible.

Re-Sequencing Workflow

• We used the native barcoding kit from ONT (NBD104) to attach short 24 base pair nucleotide sequences to uniquely identify the DNA from 3 RILs (RIL30, RIL43, RIL 81; see Figure 2) and

• All 4 samples were pooled and sequencing adapters ligated to

• Loaded on a minION flow cell that ran for 22+ hours (Figures 4

Figure 4 The number of chunks of DNA (i.e. reads) that were sequenced by the minION for the 4 strains.
